

SDN-Based DoS Attacks and Mitigation Project

Student Name: Cuneys Terzi

Email: cterzi@asu.edu

Submission Date: 6/21/2026

Class Name and Term: CSE548 Summer 2026

I. PROJECT OVERVIEW

As the data plane and control plane are separate in an SDN, some devices in the network initially do not have the knowledge of all the policies and need to forward the incoming packets to the controller to get the routing policy of that specific source-destination pair. This creates a gap in security where the system can be bogged down if a big number of packets could be forced to forward to the controller, resulting in an unresponsive, resource deprived system. To mitigate such attacks, the firewall logic in the script file can be modified to detect such a pattern that would result in forwarding too many packets to the controller. In this project, I will demonstrate the attack being successful and how the logic can be enhanced to prevent these attacks by observing any unusual source-destination relationships and blocking any source MAC address that is associated to more than one IP address, which is a sign of spoofed packets. Once a drop rule is added for that address, the rest of the packets will be dropped without ever being forwarded to the controller.

II. NETWORK SETUP

III. SOFTWARE

- Ubuntu 22.04 LTS (ARM64) virtual machine.
- Mininet network emulator
- Docker
- Open vSwitch (OVS) — the OpenFlow-enabled data-plane switch (s1)
- POX
- ovs-ofctl / ovs-vsctl — Open vSwitch
- hping3

IV. PROJECT DESCRIPTION

Step 1 : Copy project files

```
# topology script in the home directory
~/mininet_topo.py

# firewall component in the POX forwarding folder
~/pox/pox/forwarding/L3Firewall.py

# both config files in the POX root directory
~/pox/l2firewall.config
~/pox/l3firewall.config
```

Step 2 : Start POX Controller

We launch the POX controller from the command line first using the default l2_learning algorithm. This will not drop any packets by default and thus is vulnerable to DDOS attacks.

```
sudo ./pox.py openflow.of_01 --port=6655 pox.forwarding.l2_learning
```

```
vboxuser@SDN: /home/ubuntu/pox/pox$ sudo ./pox.py openflow.of_01 --port=6655 forwarding.l2_learning
POX 0.7.0 (gar) / Copyright 2011-2020 James McCauley, et al.
WARNING:version:POX requires one of the following versions of Python: 3.6 3.7 3.8 3.9
WARNING:version:You're running Python 3.10.
WARNING:version:If you run into problems, try using a supported version.
INFO:core:POX 0.7.0 (gar) is up.
INFO:openflow.of_01:[00-00-00-00-00-01 2] connected
```

Step 3 : Start Mininet network

We run the mininet_topo.py script that will create the objects that make up the mininet hosts and the switch. The execute permission on the py file was set after copying the file so we can directly execute it.

```
sudo python3 ./mininet_topo.py
```

```

vboxuser@SDN: /home/ubuntu
vboxuser@SDN:/home/ubuntu$ sudo python3 mininet_topo.py
--controller
--switch
--hosts
--links
--starting network
*** Configuring hosts
h1 h2 h3 h4
*** Starting controller

--connectivity
*** Ping: testing ping reachability
h1 -> h2 h3 h4
h2 -> h1 h3 h4
h3 -> h1 h2 h4
h4 -> h1 h2 h3
*** Results: 0% dropped (12/12 received)
*** Starting CLI:
mininet>

```

Step 4: Perform the Flood

```
h1 hping3 192.168.2.20 -c 10000 -S --flood --rand-source -V
```

hping3 has two switches which make the ddos attack possible and they are -flood and -rand-source. -rand-source especially randomizes the source Ip of the packets it sends so they look like they come from different sources. this ensures each of these packets get sent to the controller for any matching policies.

A ping from the other two hosts end up throwing the error that “Destination host unreachable” which proves the point that the controller has been overflowed with too many packets to process.

```
vboxuser@SDN: /home/ubuntu
--hosts
--links
--starting network

From 192.168.2.30 icmp_seq=1 Destination Host Unreachable
From 192.168.2.30 icmp_seq=2 Destination Host Unreachable
From 192.168.2.30 icmp_seq=3 Destination Host Unreachable

--- 192.168.2.40 ping statistics ---
3 packets transmitted, 0 received, +3 errors, 100% packet loss, time 2044ms
pipe 3
mininet>

```

Step 5 : Mitigate DoS Attack by implementing port security in accordance with pseudocode posted in Task 3.0 in L3Firewall.py

Initiate a port table (PT);

For any newly received flow, F originated from the source MAC address F.SrcMAC;

if F.SrcIP is new;

update PT with the mapping F.SrcMAC <--> F.SrcIP;

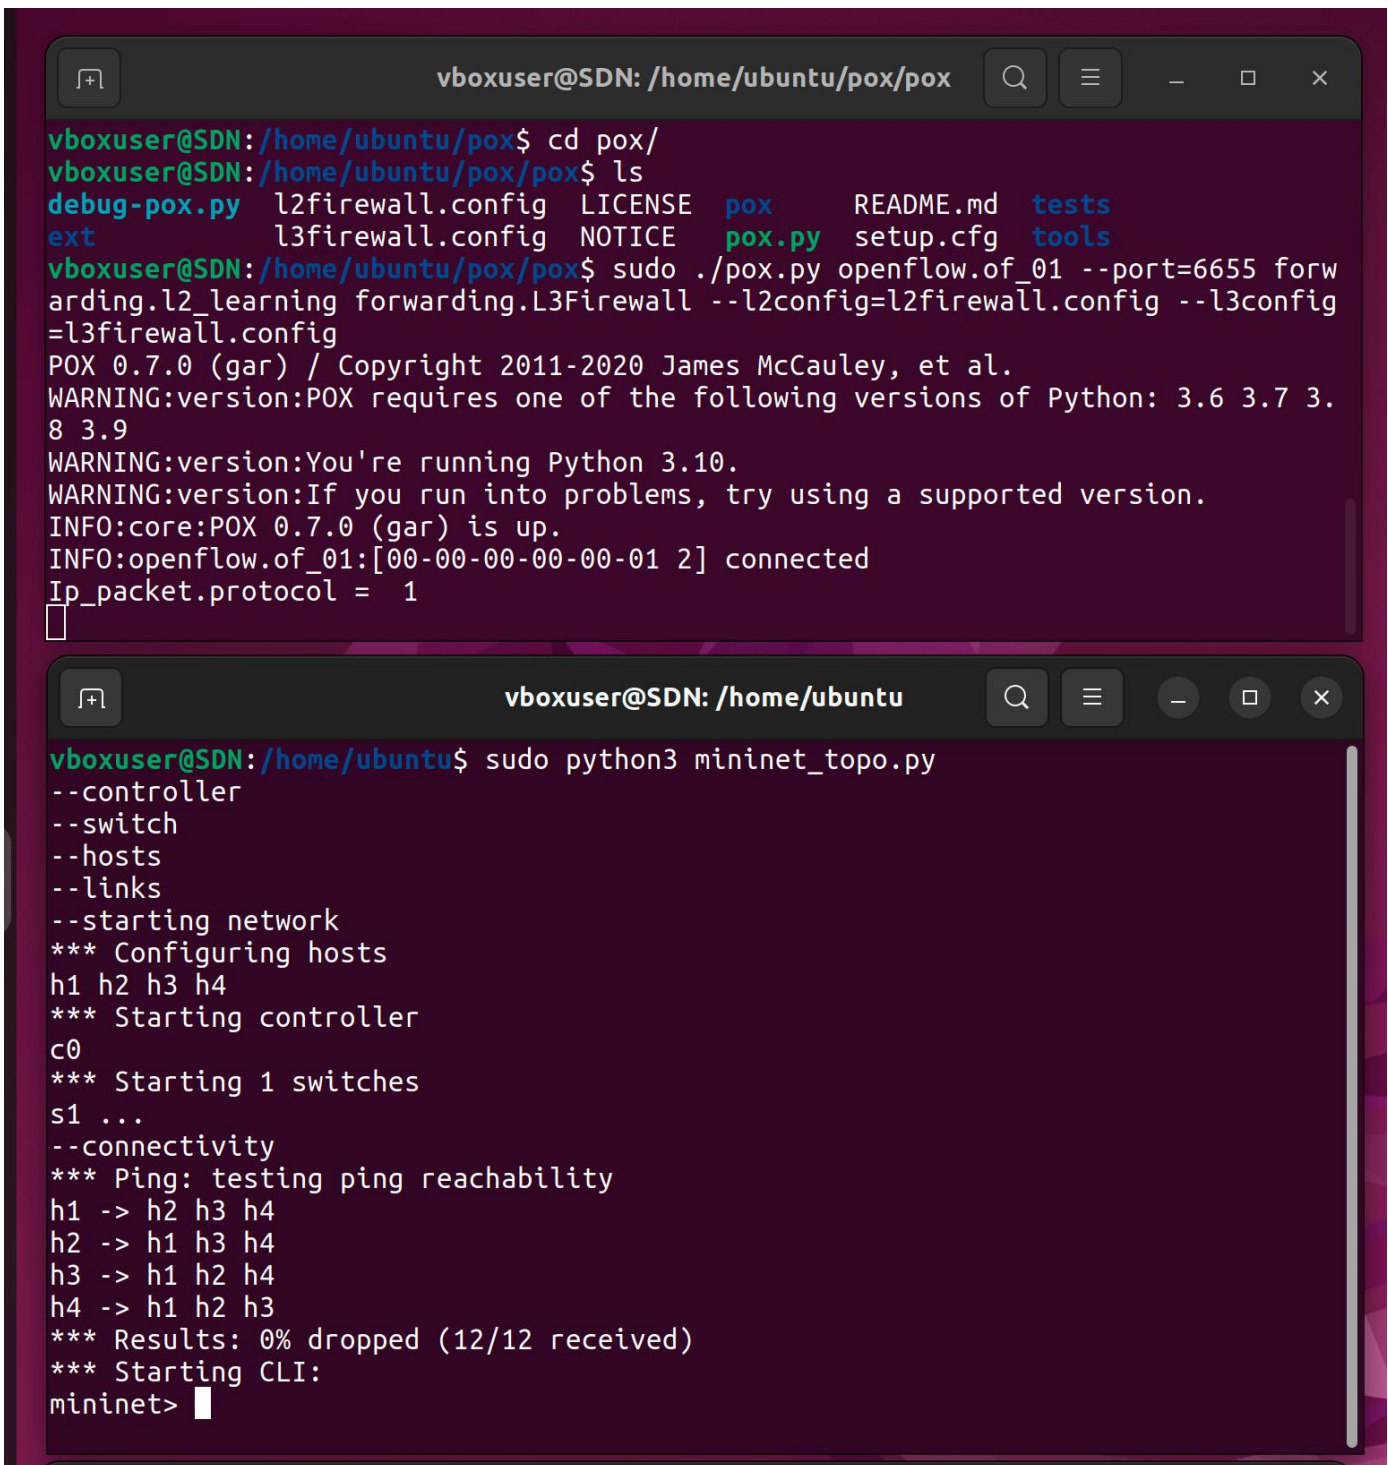

else

block F.SrcMAC % Block a MAC address that had spoofed multiple IP addresses

end

For testing the mitigation code, we have updated the L3Firewall.py code with the above logic. It simply keeps track of a MAC address-sourceIP pair and makes sure each MAC address is only matched with one IP. The relevant portions of the code can be found below.

You can find below the mitigation code in action. After starting pox.py with the L2 and L3 config parameters and L3Firewall.py code, I started the mininet and it's ready for testing the flood.

The image shows two terminal windows. The top window is titled 'vboxuser@SDN: /home/ubuntu/pox/pox' and shows the user navigating to the 'pox' directory, listing files, and running './pox.py openflow.of_01 --port=6655 forwarding.l2_learning forwarding.L3Firewall --l2config=l2firewall.config --l3config=l3firewall.config'. The output shows POX 0.7.0 (gar) is up and connected to the openflow.of_01 controller. The bottom window is titled 'vboxuser@SDN: /home/ubuntu' and shows the user running 'sudo python3 mininet_topo.py'. The output shows the configuration of hosts (h1, h2, h3, h4), starting the controller (c0), and starting switches (s1). It also shows connectivity tests (ping) and results (0% dropped).

```
vboxuser@SDN: /home/ubuntu/pox/pox$ cd pox/

V. CONCLUSION

The most important lesson I learned from this assignment is that the separation and the physical distance between the control mechanism and the execution device opens up an attack surface and it's relatively easy to create a successful DDOS attack using basic methods. This brings us to the concept of planing, code based configurations and review pipeline being very important.

Being able to use a modern programming language to be able to write logic gives the programmer a lot of power in terms of flexibility defining the security policies.

The DDOS attack that is the goal of this project was mitigated by keeping track of the mac address - ip address pairs and immediately updates the drop rule in the switch to drop further packets from that mac address as soon as it detects the second source IP from the same mac address.
